

# Arcade SDK Publishing Infrastructure

This document describes the infrastructure provided by the Arcade SDK for publishing build assets.

## What is V1 publishing?

The publishing infrastructure has multiple stage(s), these stages represent available channels. Only the stages corresponding to the default channel will execute. This is for arcade3.x only.

V1 came into existence when we branched for release/3.x in arcade. Main and arcade/3.x initially had the same publishing logic. Over time the publishing stage in arcade main evolved so that became V2 publishing.

Asset manifest Example :

publishingVersion is not present in V1.

```
<Build Name="https://dnceng@dev.azure.com/dnceng/internal/_git/dotnet-arcade-validation"
BuildId="20200915.7"
Branch="refs/heads/release/3.x"
Commit="0f733414ac0a5e5d4b7233d47851a400204a7cac"
AzureDevOpsAccount="dnceng"
AzureDevOpsBranch="refs/heads/release/3.x"
AzureDevOpsBuildDefinitionId="282"
AzureDevOpsBuildId="816405"
AzureDevOpsBuildNumber="20200915.7"
AzureDevOpsProject="internal"
AzureDevOpsRepository="https://dnceng@dev.azure.com/dnceng/internal/_git/dotnet-arcade-validation"
InitialAssetsLocation="https://dev.azure.com/dnceng/internal/_apis/build/builds/816405/artifacts"
IsStable="False"
Location="https://dotnetfeed.blob.core.windows.net/arcade-validation/index.json">
```

All the 3.1 servicing branches of repos use this version of the infrastructure.

## What is V2 publishing?

V2 is a legacy publishing infrastructure that is no longer utilized. It's essentially V1 publishing with explicit publishing version info. It uses a stage per channel and repositories must take Arcade updates to get publishing updates (e.g. new channels or fixes).

## What is V3 publishing?

In V3, a single job or stage 'Publish Using Darc' handles all publishing for all available channels. Even if the repo branch is associated to more than one default channel(s) there will be only one stage. V3 uses darc

`add-build-to-channel` to promote builds based on the current configured default channels for the branch just built. The maestro promotion pipeline is a pipeline used to publish the packages to the target channel(s). `Add-build-to-channel` queues a new build of this pipeline and waits for it to publish assets to the appropriate locations. The publishing job is run against Arcade's main branch by default, meaning that repositories do not need to take an Arcade update to be able to publish to newly created channels or get most publishing fixes.

Example from arcade-validation:

V3-publishing

Figure 1: V3-publishing

## Basic onboarding scenario for new repositories to the current publishing version (V3)

In order to use the new publishing mechanism, the easiest way to start is by turning your existing build pipeline into an AzDO YAML stage, and then making use of a YAML template (`eng/common/templates/post-build/post-build.yml`) provided by Arcade to use the default publishing stages. The process is explained below step by step.

1. Update the Arcade SDK version used by the repository to `5.0.0-beta.20461.7` or newer.
2. Disable asset publishing during the build. There are two common situations here. Some build definitions make use of the `jobs.yml` template and others make use of the `job.yml` (singular). The former is a wrapper around a few things, among them the `job.yml` and `publish-build-assets.yml` templates. If your build definition doesn't use `jobs.yml` you'll need to directly pass the `PublishUsingPipelines` parameter to the included templates. See examples below.

1. If the build job uses the `eng\common\templates\jobs\jobs.yml` template, set the parameter `enablePublishUsingPipelines` to `true`. See example below:

```
jobs:
- template: /eng/common/templates/jobs/jobs.yml
  parameters:
    enablePublishUsingPipelines: true
```

2. If the build job makes direct use of `eng\common\templates\job\job.yml` you will have to do the following changes.

1. Set the `enablePublishUsingPipelines` parameter to `true` when instantiating `job.yml`:

```

jobs:
...
- template: /eng/common/templates/job/job.yml
  parameters:
    ...
    enablePublishUsingPipelines: true
    ...

```

2. Make sure that you use the template `eng\common\templates\job\publish-build-assets.yml` to inform Maestro++ that *all* build jobs have finished executing. Also, make sure that you are setting the template parameter `enablePublishUsingPipelines` to `true`:

```

jobs:
...
- ${{ if and(ne(variables['System.TeamProject'], 'public'), notin(variables['Build.Reason'], 'PullRequest')) }}
- template: /eng/common/templates/job/publish-build-assets.yml
  parameters:
    ...
    publishUsingPipelines: true
    ...

```

3. You'll also need to pass the below MSBuild property to the Arcade build scripts.

Name	Value
/p:DotNetPublishUsingPipelines	true

For example, if the repo has the following configuration for invoking `cibuild.cmd`:

```

- _InternalBuildArgs: /p:DotNetSignType=$(SignType)
  /p:TeamName=$(TeamName)
  /p:DotNetSymbolServerTokenMsdl=(microsoft-symbol-server-pat)
  /p:DotNetSymbolServerTokenSymWeb=(symweb-symbol-server-pat)
  /p:OfficialBuildId=$(BUILD.BUILDNUMBER)

- script: eng\common\cibuild.cmd
  -configuration $(BuildConfig)
  -prepareMachine
  $(_InternalBuildArgs)

```

after setting the needed MSBuild properties it should look like this:

```

“YAML - _InternalBuildArgs: /p:DotNetSignType=(signType)/p : TeamName=(TeamName) /p:DotNetSymbolServerTokenMsdl=(microsoft-symbol-server-pat)/p : DotNetSymbolServerTokenSymWeb=(symweb-

```

```
symbol-server-pat) /p:OfficialBuildId=(BUILD.BUILDNUMBER)/p :
DotNetPublishUsingPipelines=(_PublishUsingPipelines)
```

```
- script: eng\common\cibuild.cmd
  -configuration $(_BuildConfig)
  -prepareMachine
  $(_InternalBuildArgs)
```

1. Transform your existing build-definition to a single stage. Do that by nesting the current

```
```YAML
jobs:
- template: /eng/common/templates/jobs/jobs.yml
  parameters:
    enablePublishUsingPipelines: true
...
```
```

should be changed to:

```
```YAML
stages:
- stage: build
  displayName: Build
  jobs:
  - template: /eng/common/templates/jobs/jobs.yml
    parameters:
      enablePublishUsingPipelines: true
...
```
```

We suggest you to use the stage name *\*build\** and have only one build stage. However, that

1. Import the `eng\common\templates\post-build\post-build.yml` Arcade template at the end of

```
```YAML
- ${{ if and(ne(variables['System.TeamProject'], 'public'), notin(variables['Build.Reason'], 'Build.Reason')) }}
  - template: eng\common\templates\post-build\post-build.yml
    parameters:
      publishingInfraVersion: 3
      enableSourceLinkValidation: false
...
```
```

The `post-build.yml` template accepts the following parameters:

| Name                                    | Type    | Description  |
|---|---------|--|
| publishingInfraVersion                  | int     | Publishing infrastructure version                        |
| enableSourceLinkValidation              | bool    | Run SourceLink validation during the build               |
| enableSigningValidation                 | bool    | Run signing validation during the build                  |
| enableNuGetValidation                   | bool    | Run NuGet package validation tool                        |
| symbolPublishingAdditionalParameters    | string  | Additional arguments for the Publishing stage            |
| artifactsPublishingAdditionalParameters | string  | Additional arguments for the Publishing stage            |
| signingValidationAdditionalParameters   | string  | Additional arguments for the Signing stage               |
| publishInstallersAndChecksums           | bool    | Publish installers packages and checksums                |
| SDLValidationParameters                 | object  | Parameters for the SDL job template                      |
| validateDependsOn                       | [array] | Which stage(s) should the validation stage depend on.    |
| publishDependsOn                        | [array] | Which stage(s) should the publishing stage(s) depend on. |

After these changes the build job(s) will publish the build assets to Azure DevOps build artifacts.

Examples of the use of the basic onboarding scenario can be found in the following repos:

- \* [Arcade] (<https://github.com/dotnet/arcade/blob/main/azure-pipelines.yml>)
- \* [Arcade-Validation] (<https://github.com/dotnet/arcade-validation/blob/main/azure-pipeline.yml>)
- \* [Arcade-Services] (<https://github.com/dotnet/arcade-services/blob/main/azure-pipelines.yml>)

2. Create or update eng/Publishing.props, adding the following MSBuild property:

```

```XML
  <PublishingVersion>3</PublishingVersion>
```

```

Sample:

```

```XML
  <Project>
    <PropertyGroup>
      <PublishingVersion>3</PublishingVersion>
    </PropertyGroup>
  </Project>
```

```

Example of the use of Publishing.props can be found in the following repos :

- \* [Arcade-Validation] (<https://github.com/dotnet/arcade-validation/blob/6009d37b7ecacbb0bc1e/eng/Publishing.props>)

The pipeline for a build with stages enabled will look like the one shown below.

! [V3-publishing] (./images/V3-publishing.PNG)

### Validating the changes

Since the post-build stages will only trigger during builds that run in the internal project

1. Create a branch on the Azure DevOps internal mirror of the repo that includes the pipeline
1. Set up the "General Testing Channel" as a default channel for the internal repo + branch

```
``` Powershell
darc add-default-channel --channel "General Testing" --branch "<my_new_branch>" --repo "ht
```
```

1. Queue a build for your test branch
1. Once the Build and Validate Build Assets stages complete, the \*Publish Using Darc\* stage

### ### Checksum generation

Arcade also includes support for automatically generating checksum files. To opt in to this

Example:

```
```XML
<ItemGroup>
  <GenerateChecksumItems Include="@(<OutputFile>)">
    <DestinationPath>%(<FullPath>).Sha512</OutputPath>
  </GenerateChecksumItems>
</ItemGroup>
```
```

Ensure that you do not set `publishInstallersAndChecksums=false` in your call to the `post-b

### ## Enabling 'faster' publishing

There are generally two shapes for official builds:

- Build -> Publish to Build Asset Registry -> Validate Assets (SDL, NuGet, etc.) -> Publish
- Build -> Publish to Build Asset Registry -> Publish

In the second case, the use of an additional stage and job for publishing is superfluous. In

### ### Eligibility

A build is eligible for faster publishing if:

- It does not wish to gate publishing on any logic after 'Publish to Build Asset Registry' -
- It is on V3 publishing - This is the case for all repos beyond .NET Core 3.1.

### ### Enabling fast publishing

1. **\*\*Set the parameter on post-build.yml\*\*** - In your call to the post-build.yml template, p
2. **\*\*Enable publishing during the Publish to Bar job\*\*** -

- **\*\*If you are using the jobs.yml template\*\*** - Pass parameter ``publishAssetsImmediately: true``
- **\*\*If you explicitly call publish-build.assets.yml\*\*** - Pass parameter ``publishAssetsImmediately: true``

## More complex onboarding scenarios

### Integrating custom publishing logic

Repositories that make direct use of tasks in `Tasks.Feed` to publish assets during their `*build*` task.

However, if for some reason the infra in the default publishing stages don't meet your requirements.

**\*\*Note:\*\*** We strongly suggest that you discuss with the *.Net Engineering* team the intended use case.

## PublishingUsingPipelines & Deprecated Properties

Starting with Arcade SDK version **\*\*5.0.0-beta.20120.2\*\*** there is no support anymore for the `DotNetPublishUsingPipelines` property.

- **\*\*The build definition sets ``/p:DotNetPublishUsingPipelines=true``\*\*** Arcade will handle the publishing.

| Property                      |  |
|-------------------------------|--|
| DotNetPublishBlobFeedKey      |  |
| DotNetPublishBlobFeedUrl      |  |
| DotNetPublishToBlobFeed       |  |
| DotNetSymbolServerTokenMsdl   |  |
| DotNetSymbolServerTokenSymWeb |  |

- **\*\*The build definition doesn't set ``/p:DotNetPublishingUsingPipelines`` or set it to false\*\***

| Property                 |  |
|--------------------------|--|
| DotNetPublishBlobFeedKey |  |
| DotNetPublishBlobFeedUrl |  |
| DotNetPublishToBlobFeed  |  |

Furthermore, starting with Arcade SDK version **\*\*5.0.0-beta.20120.2\*\*** the default value for `DotNetPublishUsingPipelines` is `true`.

## Frequently Asked Questions

### Guiding principles of the new infra?

- **\*\*Controlled by Maestro++ Channels:\*\*** The locations where packages are published to are determined by Maestro++ channels.
- **\*\*Publishing is decoupled from the build job:\*\*** Publishing is managed by the Arcade SDK `publish-build` task.
- **\*\*Single view for building and publishing:\*\*** The new infrastructure doesn't use Release Pipeline.

### What are YAML stages?

Stages are a concept introduced by Azure DevOps to organize the jobs in a pipeline. Just as Stages are the way that Azure DevOps is bringing build and release pipelines together, and a

### Why use YAML stages for publishing?

Using stages for publishing seeks to unify the Arcade SDK build artifact publishing mechanism

- \* Clearly separate the concepts of build, test, publish and validate.
- \* Support publishing and validation errors to be reported in the build page UI.
- \* Stages can depend on each other, which provides a natural way to extend default Arcade pub

### Are there new package feeds? Which feed will be used?

Each Maestro++ channel is configured in [source](<https://github.com/dotnet/arcade/blob/main/>)

- \*\*A transport feed:\*\* used for publishing packages intended for use internally in the .Net
- \*\*A shipping feed:\*\* used for publishing packages that will be directly used by end users.
- \*\*A symbols feed:\*\* symbol packages (`.symbols.nupkg`) are published to this feed as well

The target feed will be public/private depending on whether the Maestro++ channel is public/

Each stable build (i.e., [Release Official Builds](<https://github.com/dotnet/arcade/blob/84f>))

### What benefits do I get from the new infrastructure?

There are a few benefits, but the bottom line is: you can rely on Arcade SDK and Maestro++ t

### What's this "Setup Maestro Vars" job?

Currently Azure DevOps does not support communicating "YAML variables" across stages. The re

### How will this change affect symbol publishing?

Symbol publishing to MSDL and SymWeb will be done as a regular part of publishing the build

### Can we manually assign a build to a channel?

Yes, that's possible. You need to [use Darc to do that](<https://github.com/dotnet/arcade/blob>)

### Why the build assets aren't getting published anywhere?

Most frequent cause of this is that there is no Default Channel configured for the build. [T

### Why do you need the DotNetPublishUsingPipelines parameter?

The `DotNetPublishUsingPipelines` is a flag that Arcade SDK uses to determine if the repo was

### What's PackageArtifacts, BlobArtifacts, PdbArtifacts and ReleaseConfigs for?

- **PackageArtifacts**: contains all NuGet (.nupkg) packages to be published.
- **BlobArtifacts**: contains all blob artifacts (usually .symbols.nupkg) to be published.
- **PdbArtifacts**: contains all PDB artifacts to be published to symbol servers - SymWeb &
- **ReleaseConfigs**: contains configuration files used by the post-build stages. In particu

**Note**: only packages and blobs described in at least one build manifest will be published

### Where can I see publishing logs in V1?

The publishing logs are stored inside an Azure DevOps artifacts container named `PostBuildLo

### Where can I see publishing logs in V3?

Under the `Publish Using Darc` job get the link to the newly queued build in the [Maestro pr

### How to add a new channel to use V3 publishing?

Create the channel using [darc add-channel]([https://github.com/dotnet/arcade/blob/main/Docum](https://github.com/dotnet/arcade/blob/main/Documentation)

In the Microsoft.DotNet.Build.Task.Feed/src/Model/PublishingConstants.cs file, create a new

TargetChannelConfig takes the following attributes

| Params                  | Description   | Value                         |
|-------------------------|---|-------------------------------|
| ChannelId               | Id for channel to publish   |                               |
| isInternal              | Publishing to an internal Channel or public channel                     | true or false                 |
| PublishingInfraVersion  | Which version of the publishing infra can use this configuration.       |                               |
| AkaMSChannelName        | The name that should be used for creating Aka.ms links for this channel |                               |
| TargetFeedSpecification | List of feeds to publish (type of asset -> feed mapping)                |                               |
| SymbolTargetType        | Publish to MSDL or SymWeb symbol server                                 | PublicAndInternalSymbolTarget |
| FileNamesToExclude      | List of files to exclude from creating aka.ms links. Should be exact    |                               |
| Flatten                 | Whether or not to flatten the path when creating the aka.ms links       | Defaults to                   |

```C#

Eg:

Publishing to General Testing channel : General Testing

```
// "General Testing",
```

```

new TargetChannelConfig(
    529,
    false,
    PublishingInfraVersion.Latest,
    "generaltesting",
    GeneralTestingFeeds,
    PublicAndInternalSymbolTargets),

```

### Which feeds does Arcade infra publish to?

| Feed Name           | Intended Usage                                                                                                                                                                                                                                                                        |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dotnet-eng          | Packages required for engineering infra<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet-eng/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet-eng/nuget/v3/index.json</a>                                                        |
| dotnet-tools        | Tooling packages, such as Symreader, Sourcelink, etc...<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet-tools/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet-tools/nuget/v3/index.json</a>                                    |
| dotnet5             | .NET 5 shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet5/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet5/nuget/v3/index.json</a>                                                                             |
| dotnet5-transport   | .NET 5 non-shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet5-transport/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet5-transport/nuget/v3/index.json</a>                                                     |
| dotnet3.1           | .NET Core 3.1 shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1/nuget/v3/index.json</a>                                                                  |
| dotnet3.1-transport | .NET Core 3.1 non-shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1-transport/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1-transport/nuget/v3/index.json</a>                                          |
| dotnet3.1-blazor    | Packages specific to Blazor 3.1 This is an example of a repo-specific feed/channel<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1-blazor/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3.1-blazor/nuget/v3/index.json</a> |
| dotnet3             | .NET Core 3 shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3/nuget/v3/index.json</a>                                                                        |
| dotnet3-transport   | .NET Core 3 non-shipping packages<br><a href="https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3-transport/nuget/v3/index.json">https://pkgs.dev.azure.com/dnceng/public/_packaging/dotnet3-transport/nuget/v3/index.json</a>                                                |

### Can the feeds be overridden?

Yes. The feeds can be overridden by adding the following options when calling `PublishArtifactsInManifest.proj`:

```

/p:AllowFeedOverrides=True
/p:InstallersFeedOverride=$(InstallersFeedOverride)

```

```
/p:ChecksumsFeedOverride=$(ChecksumsFeedOverride)
/p:ShippingFeedOverride=$(ShippingFeedOverride)
/p:TransportFeedOverride=$(TransportFeedOverride)
/p:SymbolsFeedOverride=$(SymbolsFeedOverride)
```

### How are the aka.ms links formatted?

The aka.ms links are generated using the `BuildQuality` parameter that is passed to `PublishArtifactsInManifest.proj`, and the `akaMsChannelName` parameter passed to the `TargetChannelConfig` constructor. When `akaMsChannelName` is specified, we will create aka.ms links for the assets being published to that channel. Additionally, these links are “flatten,” meaning that only the filename is used in addition to the build quality and the channel name when constructing the links. Finally, all version information is stripped from the filename. For example, if the `buildQuality` is `daily`, `akaMsChannelName` is `6.0`, `flatten` is `true`, and the filename is `dotnet-sdk-6.0.100-12345.12-win-x64.zip`, the aka.ms link generated will be `aka.ms/dotnet/6.0/daily/dotnet-sdk-win-x64.zip`.

### What build qualities are supported?

The build qualities that are supported are `daily`, `signed`, `validated`, `preview`, and `ga`. All official daily builds that publish using V3 should use the `daily` build quality. Signed and validated builds are generated by the staging process of the release process. Preview and GA links are generated at release time, on release day. All builds that have preview in the release version will be of the `preview` quality. All other builds will be marked as `GA`. GA builds do not append a build quality to the links.

### Can we exclude symbols from publishing to symbols server?

Yes.

Create a file `eng/SymbolPublishingExclusionsFile.txt` in your repo, add the file name that has to be excluded from symbol publishing in `SymbolPublishingExclusionsFile.txt`.

Eg: `tools/x86_arm/mscordaccore.dll` `tools/x86_arm/mscordbi.dll` `tools/x64_arm64/mscordaccore.dll` `tools/x64_arm64/mscordbi.dll`

During publishing, arcade will pick up `SymbolPublishingExclusionsFile.txt` and exclude the symbols mentioned in it.

Was this helpful?  

## How do I publish stable packages?

Stable packages are not published by Arcade except for dependency flow and testing purposes. Stable packages go to isolated feeds (to enable rebuilds), then repo owners push these packages to Nuget.org manually. Then these packages flow to dotnet-public feed via the mirroring process

“mermaid flowchart LR Packages[Built Packages]-->ArcadePublishing{Arcade Publishing} ArcadePublishing-->|Non-Stable|PermanantFeeds[Permanant Feeds] ArcadePublishing-->|Stable|IsolatedFeeds[Isolated Feeds] IsolatedFeeds-->DogFoodingAndDepFlow{Dog-Fooding and dependency flow} PermanantFeeds-->DogFoodingAndDepFlow Packages-->|Release final stable packages on NuGet.org|NuGet[NuGet.Org] NuGet-->|Mirroring|DotnetPublic[dotnet-public feed] DotnetPublic-->RepoUse[Repository use] DogFoodingAndDepFlow-->RepoUse
